

PATH INTEGRAL APPROACH TO QUANTUM DYNAMICS AND EIGENSTATES

MOTIVATION

Electronic structure is the key issue behind materials properties, those of atoms, molecules and solids, in all phases. The conventional approaches target on finding either the wave function or the density of the many-electron system. Both of these approaches have their pros and cons, and consequently, somewhat different subfields of applications.

The conventional approaches suffer from laborious or **insufficient description of many-body effects**, they are **restricted to zero-Kelvin temperature**, and also, **restricted to Born–Oppenheimer approximation**.

FEYNMAN PATH INTEGRALS

Feynman path integrals (PI) provide an alternative approach to quantum theory, and also, derivation of Schrödinger equation [1]. Furthermore, with the PI the time evolution of the wave function or the density matrix can be simulated [1,2], and also, stationary eigenstates and energies can be found.

Path integral approaches heal the before mentioned deficiencies of conventional *ab initio* methods.

Below, playing with the real and imaginary time, like:

$$-H\psi(x, \tau) = \frac{\partial\psi(x, \tau)}{\partial\tau} \quad \xleftarrow{\tau = it} \quad H\psi(x, t) = i\frac{\partial\psi(x, t)}{\partial t}$$

DMC

$$\psi(x, \tau) = \int_a G(x, \tau; x_a, \tau_a) \psi(x_a, \tau_a) dx_a$$

τ DMC

$$G = G_{\text{diff}} G_B$$

$$G_{\text{diff}} = C_1 \exp(-\Delta x^2/2\tau)$$

$$G_B = C_2 \exp[-(\bar{V} - E_T)\tau]$$

Everywhere real and positive!
Thus, probability interpretation and "simulation of diffusion"

This is the conventional **Diffusion Monte Carlo (DMC)**.

"Ground State of the Electron Gas" by Ceperley D.M. and Alder B.J., *Phys. Rev. Lett.* **45**, 566–569 (1980) leading to LDA parametrizations

PATH INTEGRALS IN IMAGINARY AND REAL TIME

PIMC

$$\rho(x) = \int \exp(-S[0, \beta]) Dx(\tau)$$

"period" $\beta = \tau_b - \tau_a = \frac{1}{k_B T}$

Quantum statistical physics at finite temperature $T > 0$, i.e. NVT ensemble
Free energy minimum!

Most recently, static and dynamic electric multipole (hyper)polarizabilities including rovibrational effects, and also, van der Waals coefficients have been evaluated [4 i–iv].

$$\psi(x, t) = \int_a K(x, t; x_a, \tau_a) \psi(x_a, t_a) dx_a$$

RTPI

$$K = \int \exp(iS) Dx(t) \longrightarrow K = C \exp(i\phi)$$

$$S[x_a, x_b] = \int_{t_a}^{t_b} L_x dt$$

The first real time path integral approach to find the wave function of electrons

tDMC

Complex function!
Novel "real time diffusion Monte Carlo" approach

These approaches simulate coherent **time evolution in real time or stationary eigenstates** from incoherent time evolution. This might also lead to practical **solutions to the fermion sign problem**, see reference 5.

Hooke's atom: Two electrons confined with a harmonic potential: Many-body problem

Monte Carlo simulations

QUANTUM DYNAMICS

Coherent dynamics: The modulus "vector" rotates on complex plane with increasing phase leading to the dynamics of the wave function.

EIGENSTATES

Incoherent dynamics: The rotating modulus "vector" is projected stepwise onto the real axis finally leading to the real wave function of one of the eigenstates.
